1. Introduction

This report describes the pre-construction noise analysis conducted by Hankard Environmental for the proposed Riverbend Wind Energy Facility (Project, Facility). The analysis was conducted at the request of the Project proponent, MI Energy Developments, LLC, in support of their application for a Renewable Energy or Storage Siting Certificate under the provisions of Michigan Compiled Laws (MCL) 460.1226(7)(g) Section 226(8) of Act 233. An ambient noise study was also conducted to analyze existing noise levels within and near the Project (Project Area).

The Project is expected to produce up to 300 megawatts (MW) of electric power using 50 wind turbines, all of which are to be located in Sanilac County, Michigan. Also included in the analysis is noise from the Facility substation. Figure 1-1 shows the general location of the Project, which is approximately 60 miles northeast of Detroit, Michigan.

This report describes the applicable noise regulation and implementation methods, the Project and its environs, the methodology and results of the ambient noise study, the data used to predict noise levels, and the results of the noise level predictions demonstrating compliance with the State of Michigan law.

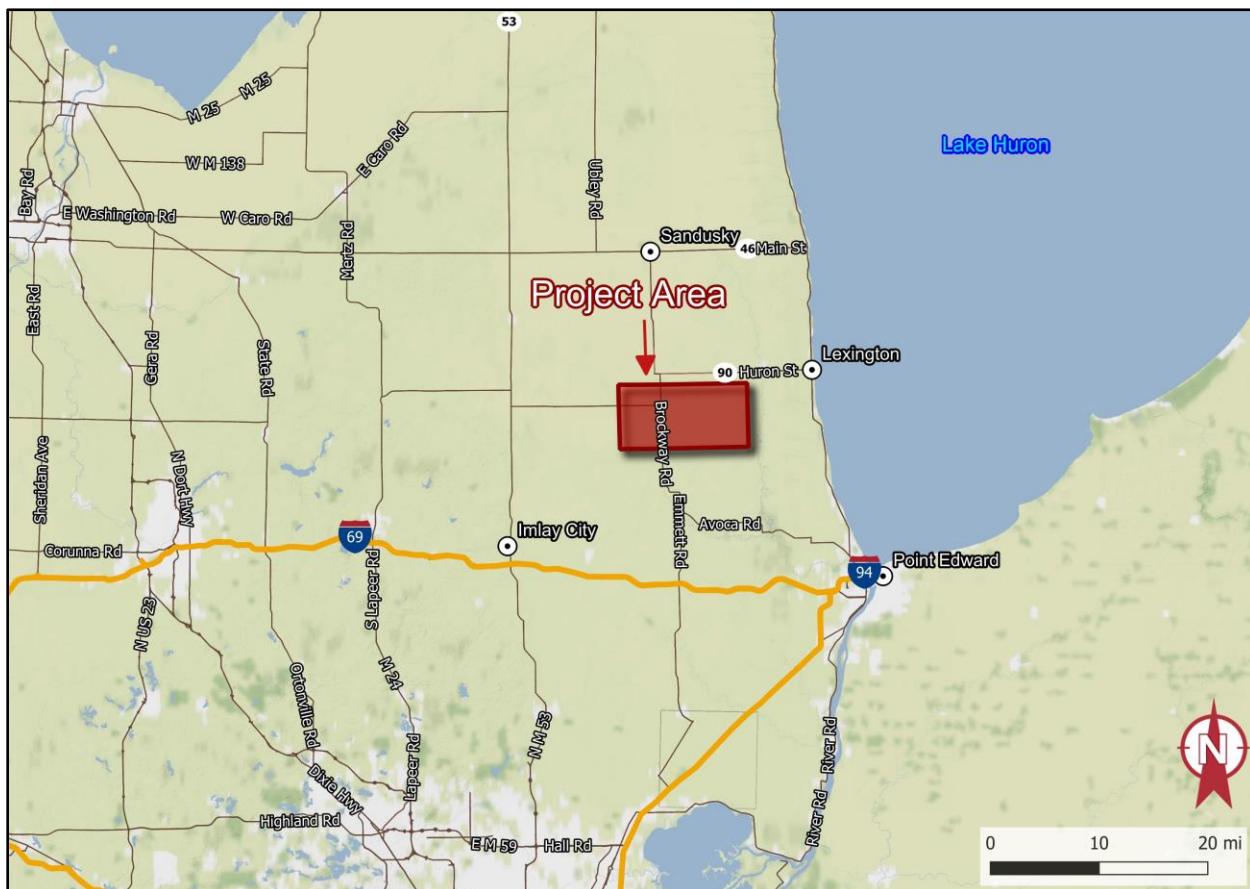

Figure 1-1. General Location of the Proposed Riverbend Wind Energy Facility

2. Applicable Noise Standards

There are no federal laws or regulations that apply to noise emissions from the Project. The Project is located in Fremont and Speaker Townships in Sanilac County, Michigan. Pursuant to Act 233, local jurisdictions with noise ordinances that are more restrictive than those defined by Michigan Compiled Laws (MCL) 460.1226 are not recognized. The Project is subject to the requirements of MCL 460.1226 Subsection (8)(b)(iv) which states:

The wind energy facility does not generate a maximum sound in excess of 55 average hourly decibels as modeled at the nearest outer wall of the nearest dwelling located on an adjacent nonparticipating property. Decibel modeling shall use the A-weighted scale as designed by the American National Standards Institute.

On October 10, 2024 the Michigan Public Service Commission (MPSC) issued PA 233 Application Filing Instructions and Procedures, which includes Attachment D - Sound Report Requirements. The Sound Report Requirements include detailed noise level modeling (prediction), measurement, and reporting guidelines. A detailed description of the noise modeling methodology used in this analysis, as it pertains to the requirements listed in the Sound Report Requirements, can be found in Section 4 below.

On October 10, 2024 the MPSC also issued Final Rules U-21547 (Order). The Order describes the following in relation to application requirements and sound modeling guidelines:

1. Minimum Qualifications for Noise Control Engineer: See Section 7, below, for a description of Hankard Environmental's qualification for conducting this noise level assessment.
2. Tonal Prominence Penalty: See Section 5, below, for a full description of Hankard Environmental's tonality assessment. For this noise level analysis, a +5 dB penalty was included in transformer sound power levels but not wind turbine sound power levels, as the turbines' noise emissions are not tonal according to ANSI S12.9 Part 4 (Annex C).
3. Façade Pressure Doubling Method: To account for façade pressure doubling, +6 dB was added to the predicted noise levels presented herein.
4. Pre-construction Sound Monitoring: A pre-construction sound survey was conducted and the results are described in Section 4.
5. Post-construction Monitoring: The required post-construction monitoring is not addressed in this preconstruction noise modeling assessment.

3. Project Description

The Project plans to install 50 wind turbines across Speaker and Fremont Townships in Sanilac County, Michigan, generating up to 300 MW of electric power. This analysis considered five different turbine models, the Vestas V162-6.0 MW turbine with a hub height of 119 meters, the Nordex 169/5.X turbine with a hub height of 112 meters, the Vestas V162-6.8 MW turbine with a hub height of 119 meters, the Vestas V162-7.2 MW turbine with a hub height of 119 meters, and the Vestas V163-4.5 MW turbine with a hub height of 118 meters. All turbines will be equipped with Serrated Trailing Edge (STE) for both the Vestas and Nordex turbines. Associated facilities include gravel access roads, underground cabling, and a substation.

The substation includes two 150 megavolt ampere (MVA) step-up transformers. Figure 3-1 shows the locations of the proposed wind turbines and substation. A table of all Project noise source locations and their coordinates is provided in Appendix A.

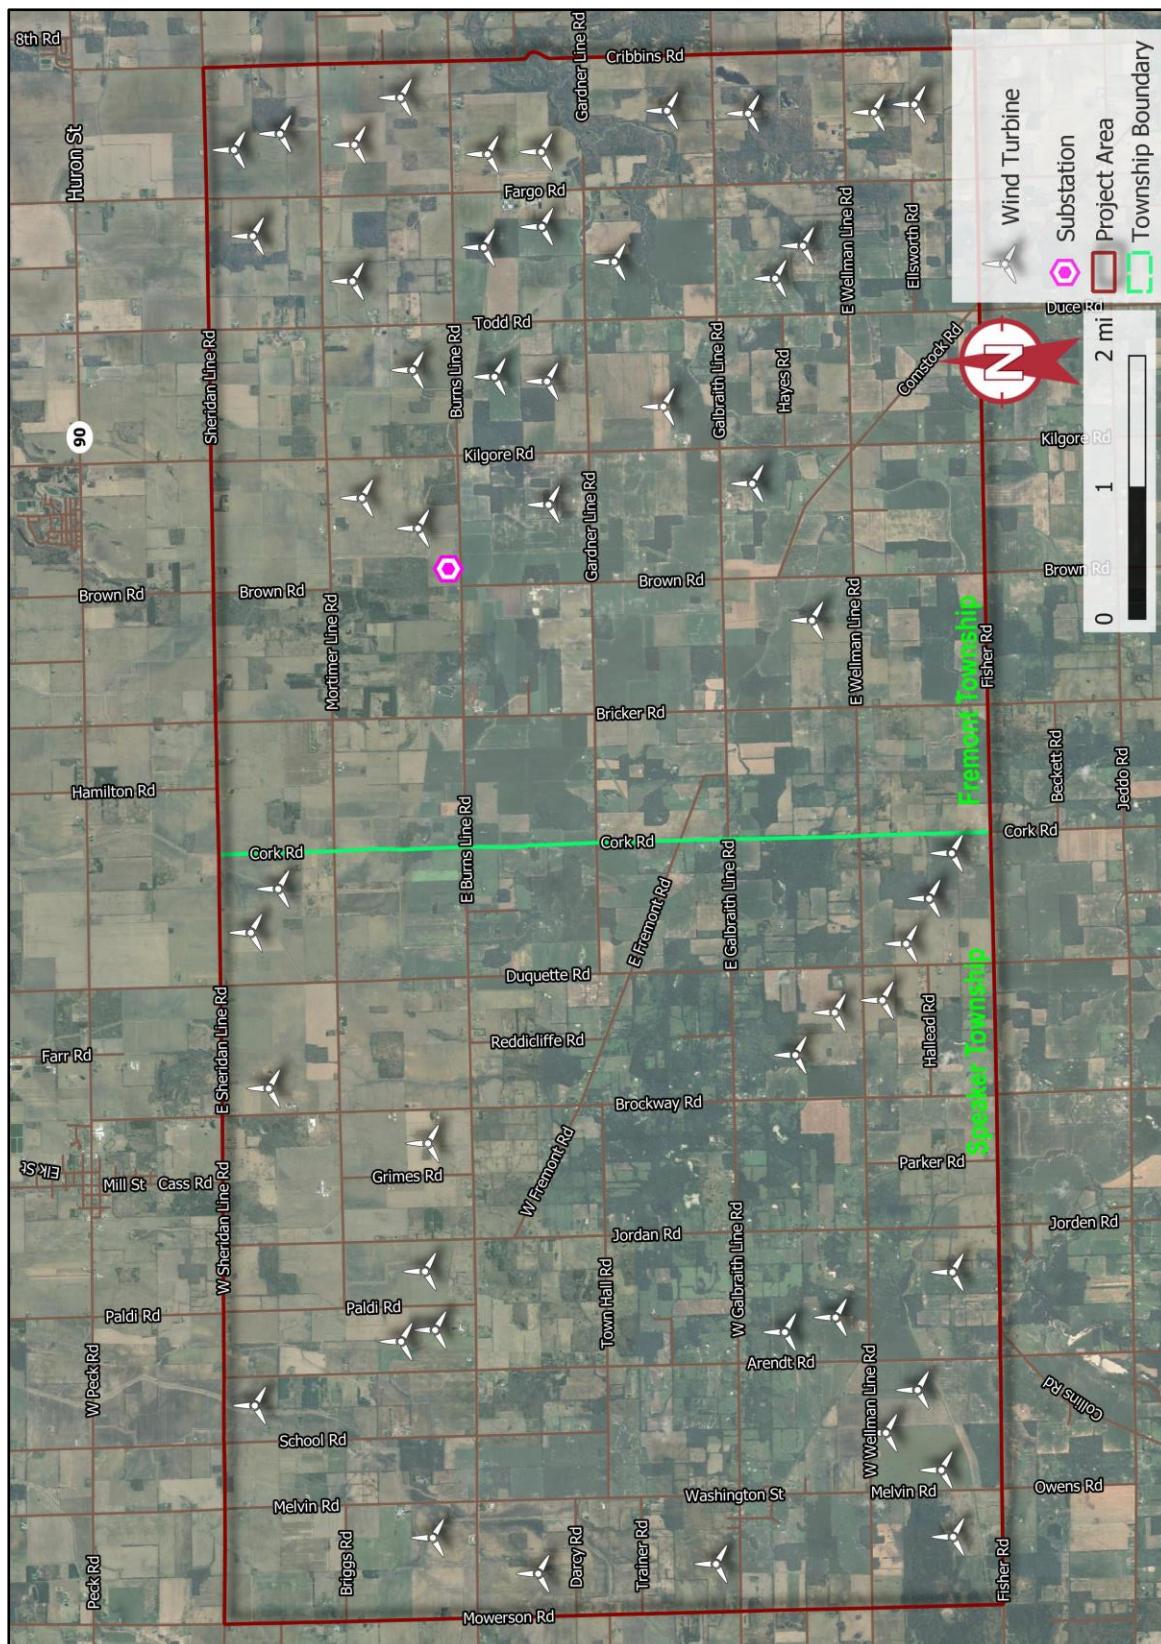

Figure 3-1. Riverbend Wind Energy Facility Layout

4. Ambient Noise Survey

An ambient noise survey was conducted in the Project Area during June and July of 2024. Noise levels were measured at six locations representative of the non-participating noise-sensitive receptors located closest to the Project. Noise measurement locations are shown in Figure 4-1. The measurement points were selected to be representative of rural non-participating residences, both close to and removed from existing sources of noise, which would be most impacted by the Project. A full description of locations, measurement and analysis methodologies, and results are provided in Appendix D.

Sources of existing noise most commonly observed included natural sounds (birds, wind), distant traffic (Galbraith Line Road and Highway 90), and local traffic. Less frequently observed noise sources included agricultural equipment, aircraft overhead, and distant dog barks. The monitors continuously recorded noise levels for 20 full days between June 25 and July 16, 2024. Existing L_{eq} noise levels (mean), during conditions conducive to full turbine operations during daytime and nighttime hours, ranged from 39 to 51 dBA and were primarily correlated with local traffic and wind gusts. Existing L_{90} noise levels during conditions conducive for full turbine operations during daytime and nighttime hours, were typically 30-40 dBA and were strongly correlated with local traffic and average wind conditions. Table 4-1 summarizes the ambient noise levels during conditions conducive to full turbine operations.

Table 4-1. Ambient Hourly Noise Levels During Conditions of Full Turbine Acoustic Emissions

Location	Mean Hourly L_{eq} (dBA)	Mean Hourly L_{10} (dBA)	Mean Hourly L_{50} (dBA)	Mean Hourly L_{90} (dBA)

Speaker Average	40	42	37	34
Site-Wide Average	43	45	39	34

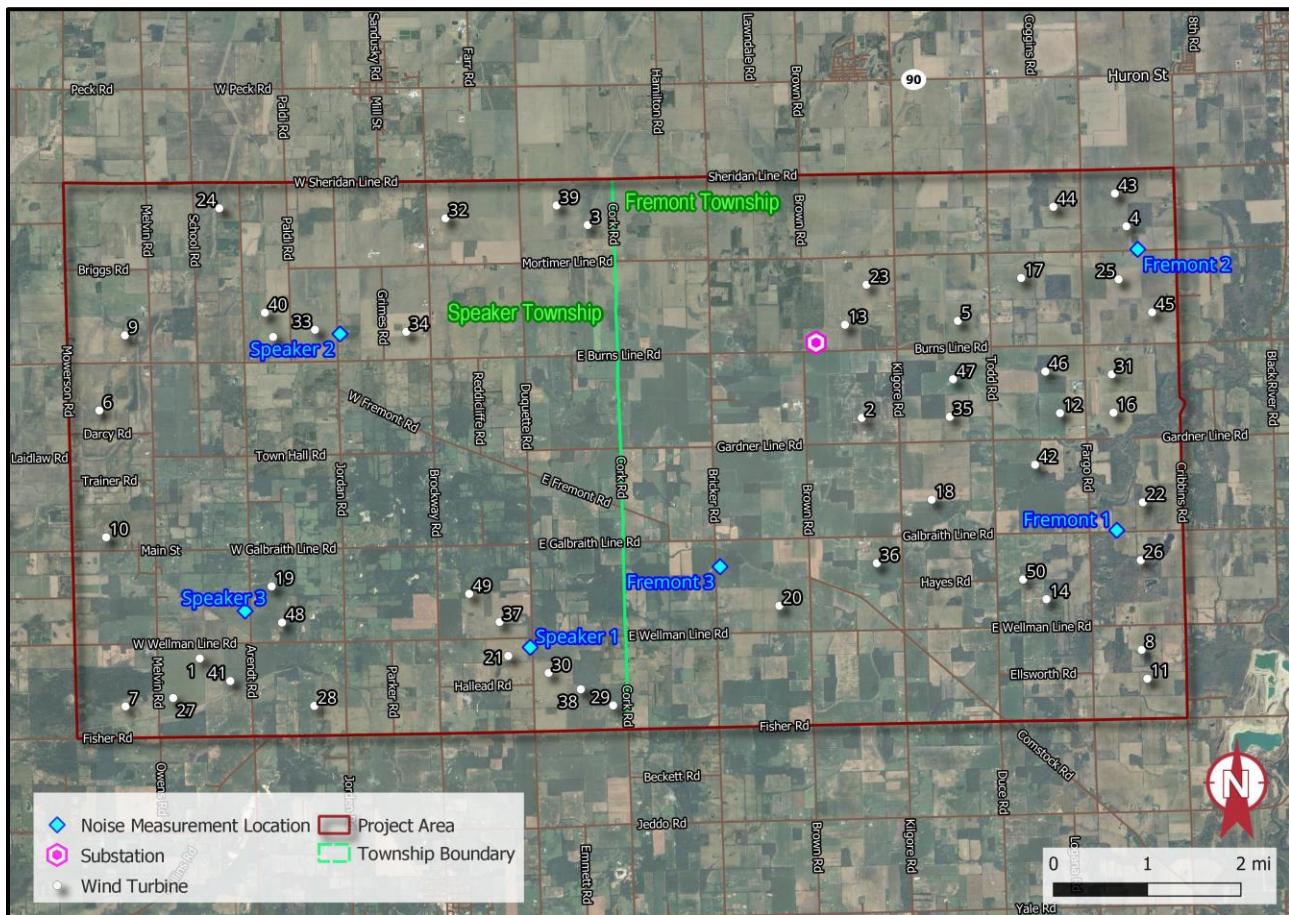

Figure 4-1. Ambient Noise Survey Measurement Locations

5. Noise Modeling Method

Noise levels from the proposed Project were predicted following the guidelines prescribed by the MPSC in PA 233 Application Filing Instructions and Procedures, Sound Report Requirements. Table 5-1, below, lists the noise level modeling requirements for wind, solar, and energy storage facilities set forth in the Sound Report Requirements, and the subsections following Table 5-1 describe how each parameter was applied for this analysis. Noise levels were predicted using the method set forth in International Organization for Standardization (ISO) Standard 9613-2:2024 - *Attenuation of Sound During Propagation Outdoors*. Modeling was implemented using the SoundPLAN v9.1 acoustical modeling program. Figure 5-1 shows a representative three-dimensional view of the SoundPLAN model of the Project.

Table 5-1. Sound Modeling Parameters

Parameter	Value
G (ground factor)	0.0 over water and large areas of hard ground, 0.5 everywhere else
Modeling uncertainty adjustment	Minimum of +2 dB for wind projects, Minimum of +0 dB for all other sources
Receptor/grid height	4.0 m for wind projects, otherwise, <ul style="list-style-type: none"> • 4.0 m for two- or more-story dwellings (default) • If sound barriers are proposed, the height of the highest window for each dwelling • 1.5 m for property boundaries and one-story dwellings
Source height	For wind turbines, hub height. For all other sources, top of the sound source
Receptors	All dwellings within 1 mile of any facility sound source
Temperature/Humidity	10°C, 70%
Sound power level	See below
Source directivity	For wind turbines, omnidirectional. For all other sources, directionality of sound power may be considered if known.
C _{met} (meteorological adjustment)	0 (none)
Include all sources within	8,000 m
Dense vegetation	No foliage attenuation allowed to be considered outside of Project-controlled parcels
Tonal prominence	+5 dB tonal penalty to source sound power. The tonal penalty can be removed if it can be shown that the facility would not have a tonal prominence at a dwelling when the measured background sound of the lowest hourly L ₉₀ is added.
Façade pressure doubling ¹	+6 dB to modeled free field outer wall sound pressure level
Other energy facilities	Other energy facilities that have an application submitted prior to this facility, approved, or built, within two miles of the facility must be included in a separate cumulative impact model run.

¹MCL 460.1226 states that the noise limit is considered "at the nearest outer wall of the nearest dwelling." In practice, this would be measured with a microphone mounted directly on the façade, that is, flush mounted on the vertical reflecting surface of a building. The pressure doubling at the surface with respect to the free-field condition leads to a 6 dB increase in sound level and is referred to as the "6-dB position" in ANSI S12.9 Part 3. Sound modeling conducted using ISO 9613-2 does not include the +6 dB adjustment. Therefore, 6 dB must be added to the sound modeling results to reflect what would be measured at the façade.

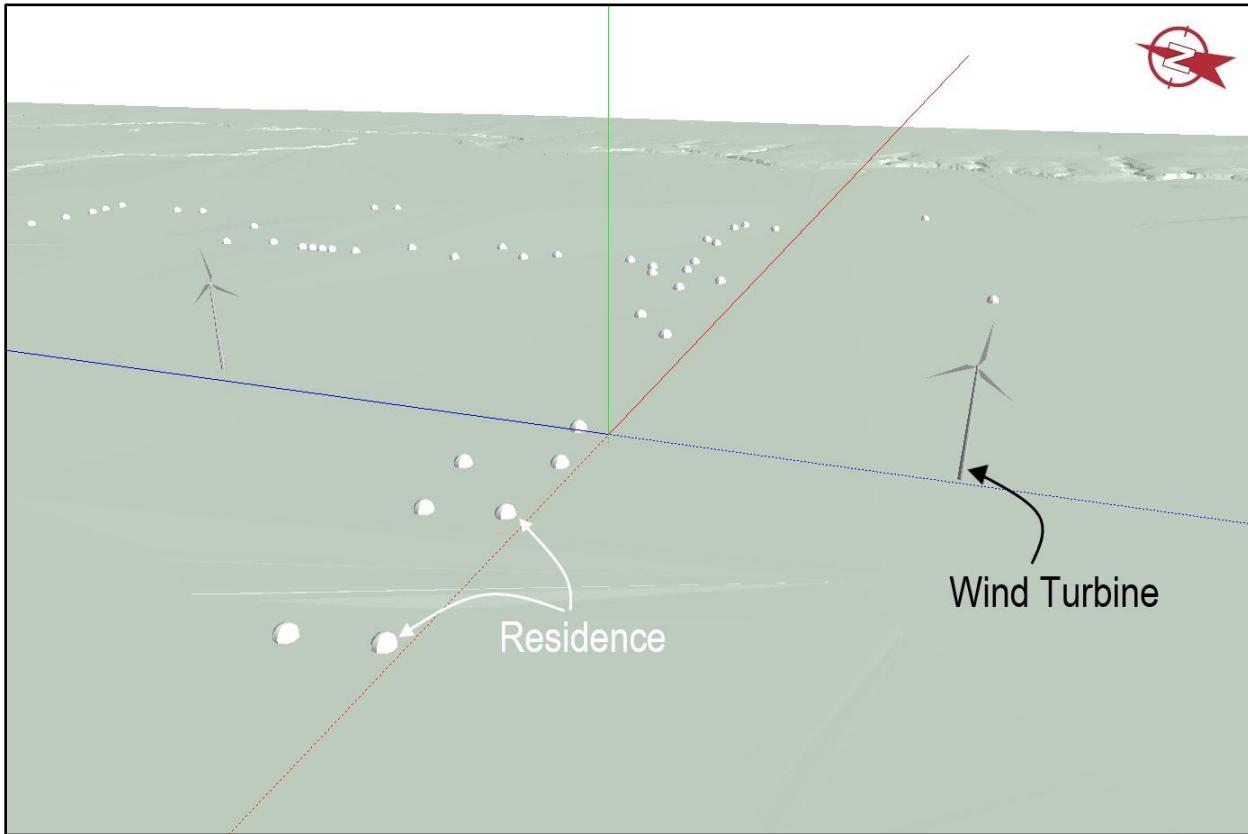

Figure 5-1. Three-Dimensional View of the SoundPLAN Noise Model

Ground Factor

The ground absorption factor was set to 0.5.

Modeling Uncertainty Adjustment

An uncertainty factor of +2 dBA was added to all predicted noise levels.

Receptors / Grid Height

In the SoundPLAN model receptor points were placed at each of the 1,469 residences (including 131 participants and 1,338 non-participants) located within approximately 1.25 miles of any Project noise source. The geographic locations of the receptors were obtained from the Project and are listed in Appendix B. The height of each receptor was set to 4 meters above the ground. Noise level contours were also generated to help graphically illustrate how predicted noise levels vary within the Project area. The height above ground for the noise level contours was also set to 4 meters.

Source Height, Sound Power Level, Source Directivity

In the SoundPLAN model, each turbine was represented as an acoustical point source located at its hub height propagating equally in all directions. The geographic coordinates, ground elevation, and source height for each turbine and substation transformer, as well as the

transformer size, are listed in Appendix A. The analysis considered five different turbine models, the Vestas V162-6.0 MW turbine with a hub height of 119 meters, the Nordex 169/5.X turbine with a hub height of 112 meters, the Vestas V162-6.8 MW turbine with a hub height of 119 meters, the Vestas V162-7.2 MW turbine with a hub height of 119 meters, and the Vestas V163-4.5 MW turbine with a hub height of 118 meters. All turbines will be equipped with Serrated Trailing Edge (STE) blades for both the Vestas and Nordex turbines. All turbines were assumed to be operating in full, continuous, and normal mode (versus noise-reduction mode).

Table 5-2 lists the overall A-weighted sound power levels used in the model for each source. The noise emission levels of each turbine were provided by the manufacturer and were determined according to International Electrotechnical Commission Standard 61400-11. In accordance with the Sound Report Requirements, this analysis used the sound power levels reported by the manufacturer for a wind speed of 10 m/s at hub height, which is the wind speed at which maximum acoustic emissions occur.

The Project includes a substation that will contain two 150 MVA step-up transformers, which are the only significant noise-producing equipment. The noise analysis assumed the simultaneous operation of both transformers, including the operation of the cooling fans. The sound power levels from the step-up transformers are listed in Table 5-2. The transformers were modeled as point sources located two meters above the ground, with no barriers or directivity reductions. The sound level of the transformers was estimated using the procedures outlined in the Institute of Electrical and Electronics Engineers (IEEE) Standard C57.12.90-2021. The transformers were assumed to be tonal, and thus 5 dBA was added to the sound power levels to account for this tonality, per the Sound Report Requirements.

Table 5-2. Source Sound Power Levels

Source	Source or Hub Height (meters)	Sound Power Level (dBA)
Vestas V162-6MW STE Blades	119	104.3
Nordex 169/5.X Mode 0 STE Blades	112	106.5
Vestas V162-6.8MW STE Blades	119	103.3
Vestas V162-7.2MW STE Blades	119	104.6
Vestas V163-4.5MW STE Blades	118	106.3
Transformer 150 MVA*	2	103.8

* 5 dBA tonality penalty included

Temperature/Humidity

The air temperature, relative humidity, and atmospheric pressure were set to conditions of 10°C, 70%, and 1 atmosphere, respectively. These values represent the lowest amount of atmospheric absorption of sound available in the ISO 9613-2:2024 method and result in the highest levels of sound reaching the receptors.

C_{met} (Meteorological Adjustment)

No meteorological adjustment was made for this analysis.

Source Range

All sources located within 8,000 meters of a receptor were included in the predictions.

Dense Vegetation

No attenuation due to foliage was considered for this sound level assessment.

Tonal Prominence

The assessment of tonality was conducted by applying the criterion in ANSI S12.9 Part 4 (Annex C) which looks at each one-third octave band noise level and compares it to the average of the levels in the two adjacent bands. If the differences exceed certain thresholds, the noise is considered tonal. The allowable differences are 15 dB from 25 to 125 Hz, 8 dB from 160 to 400 Hz, and 5 dB from 500 to 10,000 Hz. The one-third octave band noise levels provided by the manufacturer of each turbine were analyzed using this standard.

The wind turbines considered for this Project do not have tonal noise emissions according to ANSI S12.9 Part 4, Annex C. However, noise emissions from the Project's substation step-up transformers have the potential to be tonal and for this study are assumed tonal. As a result, 5 dBA was added to the transformer sound power levels, as shown in Table 5-2 above.

Façade Pressure Doubling

In accordance with the Sound Report Requirements, 6 dBA was added to all predicted noise levels to account for façade pressure doubling.

Other Energy Facilities

There are no other energy facilities located within two miles of the Project.

6. Predicted Noise Levels

Noise levels were predicted for the full and continuous operation of the proposed Project for each of five potential wind turbine models. Noise levels were predicted at each of the 1,469 receptors identified within approximately 1.25 miles of any proposed noise source.

- Predicted noise levels for all receptors are at or below the 55 dBA limit set forth in MCL 460.1226.
 - For the Vestas V162-6.0MW turbines with STE blades, predicted noise levels at non-participating receptors range from 35 to 53 dBA (L_{eq}).
 - For the Nordex 169/5.X turbines with STE blades, predicted noise levels at non-participating receptors range from 37 to 55 dBA (L_{eq}).
 - For the Vestas V162-6.8MW turbines with STE blades, predicted noise levels at non-participating receptors range from 35 to 52 dBA (L_{eq}).
 - For the Vestas V162-7.2MW turbines with STE blades, predicted noise levels at non-participating receptors range from 36 to 53 dBA (L_{eq}).
 - For the Vestas V163-4.5MW turbines with STE blades, predicted noise levels at non-participating receptors range from 37 to 55 dBA (L_{eq}).
 - Table 6-1 lists the predicted noise level at the loudest 15 non-participating receptors. The predicted noise levels at all receptor locations, for each turbine type, are listed in Appendix B.
- Figure 6-1 shows the results of the noise level predictions in the form of noise level contours. The areas between turbines and the 55 dBA L_{eq} noise level contours have predicted levels above 55 dBA. Those areas outside of the contours have a predicted noise level less than 55 dBA. More detailed noise level contour figures showing receptors are provided in Appendix C.
- Note that this analysis represents the very highest wind turbine noise levels expected. The noise level prediction method prescribed by the MPSC is consistent with that described by ANSI/ACP Standard 111-1 (2022): *Wind Turbine Sound Modeling*. This noise level prediction method has been validated by Hankard Environmental and other researchers and shown to overpredict measured levels by 1 to 2 dBA.
- Finally, a majority of the time wind turbine noise levels will be less than those described herein when the turbines are not producing full acoustic output due to low winds, and/or atmospheric conditions not being as conducive to sound propagation as assumed herein (e.g., unstable atmosphere, receptors crosswind to the nearest turbines).

Table 6-1. Highest Predicted Noise Levels at Non-Participating Receptors

7. Qualifications

All aspects of this study were either conducted by or directly overseen by Mr. Michael Hankard, who is the founder and owner of Hankard Environmental, Inc. Mr. Hankard has 35 years of acoustical consulting experience. He has conducted hundreds of noise measurement surveys for projects in the electrical power generation, mining, transportation, and other industries. He holds a B.S.E.E. degree from the University of Maine with a specialization in acoustics and is a full member of the Institute of Noise Control Engineering (INCE) and the Acoustical Society of America (ASA). His entire career has been dedicated to the measurement, analysis, mitigation, and compliance assessment of environmental noise.

Mr. Hankard was a member of the committee that developed the American National Standards Institute (ANSI) and American Clean Power (ACP) standard ACP 111-1 (2022), *Wind Turbine Sound Modeling*, and he is currently participating in the process to develop a national standard for the prediction of noise from energy storage projects.

APPENDIX D

Ambient Noise Level Survey

D1. Ambient Noise Measurement Procedures

A background (ambient) noise level survey was conducted in the Project Area to characterize and document pre-construction noise levels. The survey was conducted between June 25 and July 16, 2024. The measurement survey was carried out in conformance with the requirements of a protocol mutually agreed to between Riverbend Wind and the acoustic consultant hired by Speaker Township. The measurement procedures and methodologies employed are consistent with MPSC requirements.

D1.1 Measurement Locations

In general, the Project study area is rural/agricultural with a relatively low density of residences. Significant roads in the area include Galbraith Line Road, which runs east to west through the central portion of the Project, State Highway 90, which runs east to west through central and northern portions of the Project, and State Highway 19, which runs north to south bisecting the Project. Other than traffic and natural sounds (birds, insects, wind), existing sources of noise include occasional agricultural operations, aircraft overhead, and the activities of residents (e.g., lawn mowing).

Noise levels were measured at six locations representative of the non-participating noise-sensitive receptors located closest to the Project. Noise measurement locations are shown in Figure D-1 and general coordinates are provided in Table D-1. Detailed maps and photographs of each measurement location are provided at the end of this appendix. The selection of the measurement locations considered several factors, including proximity to the proposed Project turbines, proximity to existing noise sources and roadways, farm and non-farm settings and their local activities and noise sources, and access to land and equipment security. The measurement points were selected to be representative of rural non-participating residences, both close to and removed from existing sources of noise, which would be most impacted by the Project.

Also, a factor in the site selection was to achieve a relatively even geographical distribution of measurement locations across the Project area. A description of the locations is as follows:

- Fremont 1 (F1) is in the east-central portion of Fremont Township, along Fargo Road, between the intersections with Gardner Line Road and Burns Line Road.
- Fremont 2 (F2) is in the northeast portion of Fremont Township, along Mortimer Line Road, between the intersections with Fargo Road and Cribbins Road.
- Fremont 3 (F3) is located in the southwestern portion of Fremont Township, along Bricker Road, between the intersections with Galbraith Line Road and Wellman Line Road.
- Speaker 1 (S1) is located in the southeast portion of Speaker Township, along Duquette Road, near the intersection with Wellman Line Road.
- Speaker 2 (S2) is approximately centrally located in Speaker Township, along Jordan Road, near the intersection with State Highway 90.
- Speaker 3 (S3) is located near the northeastern boundary of Speaker Township, along Cork Road, between the intersections with Sheridan Line Road and Mortimer Line Road.

Table D-1. Ambient Noise Measurement Locations

Measurement Location	Easting (UTM 17)	Northing (UTM 17)

F3	358400	4782931
S1	355144	4781549
S2	351882	4786921
S3	350255	4782171

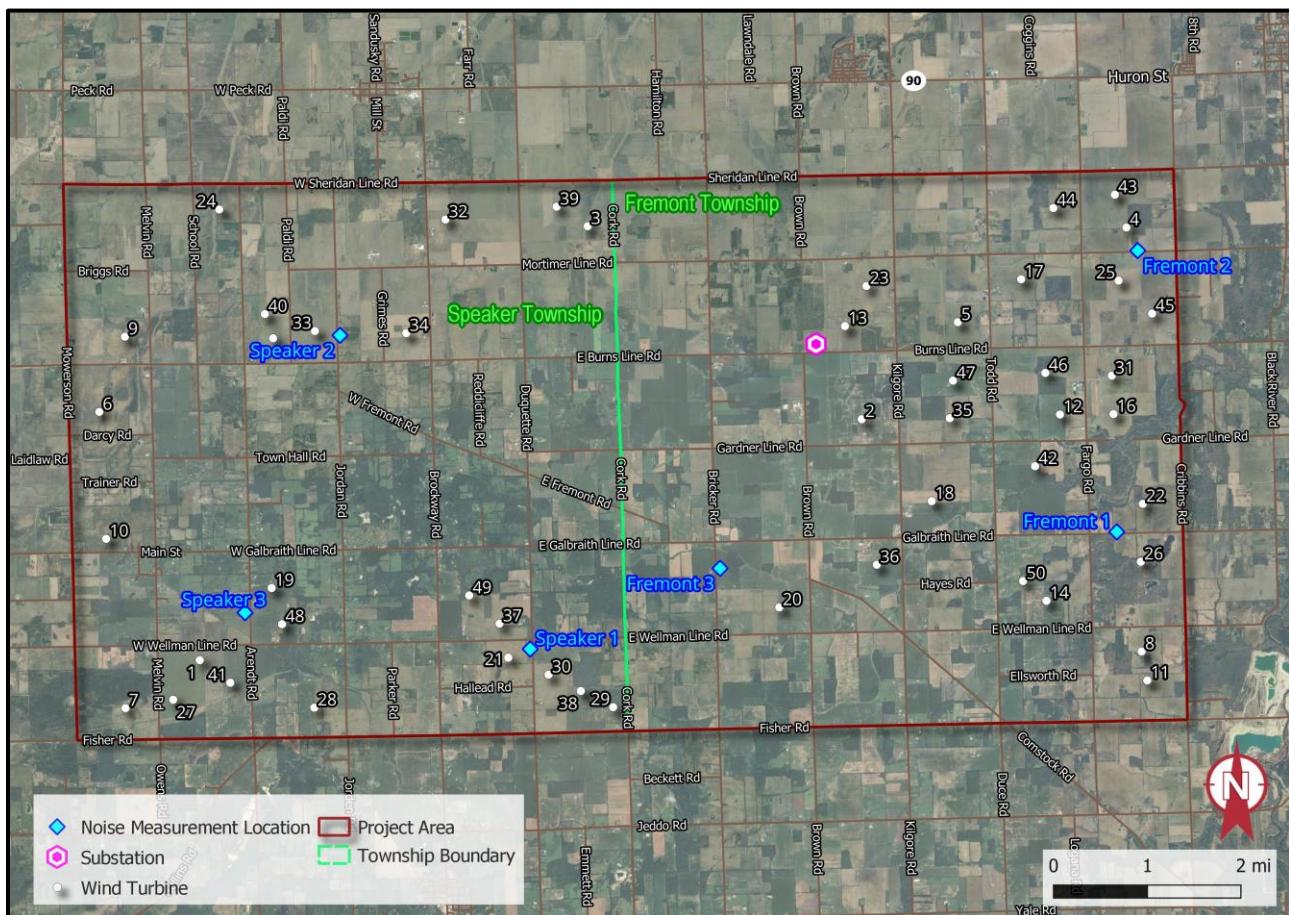

Figure D-1. Location of Project and Noise Measurement Locations

D1.2 Measurement Procedures

The long-term noise monitors continually measured ambient sound levels over the course of 20 days. For the most part, the measurement equipment was left to continuously measure noise and wind data unattended. Hankard Environmental staff made observations during daytime and nighttime hours for each visit to the Project area, noting environmental noise sources at each measurement location. These included equipment installation (June 25-26), and retrieval (July 15-16). Additionally, the Project supplied Hankard Environmental with wind speed data measured at a height of 60 meters from the Project's local meteorological tower. This data was used to

estimate when existing turbines would have been operational during the long-term measurements.

Sound levels were measured using Larson Davis models 831 meters that meet the provisions for Type 1 meters per ANSI S1.4. All sound level meters were calibrated on location prior to the measurements using a handheld calibrator and were calibrated by an accredited laboratory within 18 months of use.

The microphones were covered with hydrophobically treated, seven-inch diameter, 80 pores-per-inch density windscreens to reduce the influence of wind-induced noise. The microphones were mounted on a fixed post or tripod and positioned five feet above the ground and, with the exception of measurement location S3, at least 25 feet away from acoustically reflective surfaces per ANSI S12.9 Part 3. Due to land access, measurement location S3 was closer than 25 feet away from acoustically reflective surfaces. Wind speeds were measured continuously at the long-term monitoring sites using a Vaisala sonic anemometer.

The sound level meters were configured to collect the following data in 10-minute intervals:

- a. Unweighted octave band and one-third octave band noise levels (16 through 10,000 Hz).
- b. Overall A-weighted noise levels in the following metrics: L_{eq} , L_{10} , L_{50} , and L_{90} .

Table D-2. Noise and Meteorological Measurement Equipment

Instrument Type	Manufacturer	Model
Sound Level Meter	Larson Davis	831
Sound Level Meter	Larson Davis	831C
Preamplifier	Larson Davis	PRM831
½" Microphone	Larson Davis	377B02

Acoustic Calibrator	Larson Davis	CAL200
Wind Data	Vaisala	WXT532
Meteorological and Wind Data	Vaisala	WXT536
External Audio Recordings	Tascam	DR-05X

D1.3 Analysis Procedures

The 10-second measurement data was used to calculate one-hour statistical noise level metrics. Ten-second samples with precipitation were removed from the analysis. The results are primarily presented herein in terms of four metrics: the A-weighted L_{eq} which represents the average sound level over a given measurement interval (one hour for this analysis), the A-weighted L_{10} which represents the level exceeded 10% the measurement interval and is influenced by high-level extraneous noises such as wind gusts and local traffic, the A-weighted L_{50} which represents the level exceeded 50% of the time, and the A-weighted L_{90} which represents the level exceeded 90% of the time over the measurement interval. The L_{90} filters out sporadic noises to some degree and is representative of the quiet, consistent levels occurring within the interval.

D1.4 Ambient Noise Levels Versus Wind Speed

A unique feature of wind turbine projects, versus other industrial noise sources, is that they only operate when it is windy at the height of the rotor. When this occurs there is almost always some degree of wind at tree- and ground-level, which generates noise as it passes through vegetation (trees, shrubs, crops, etc.) The noise from vegetation rustle can, at times, mask the noise from the wind turbines. The level of noise created by the wind is a function of the wind speed and the presence of, and type of, nearby vegetation (particularly trees). In the Project area there are many residences located near or within large stands of trees.

To assess how much noise is generated by the wind the measured ambient noise levels were plotted versus the concurrently measured on-site hub-height wind speed on an hourly basis. Wind speed at hub-height was calculated by first determining the one-hour wind shear exponents using ground wind speeds measured at each measurement location and wind speeds measured by the Project's meteorological towers at a height of 60 meters above the ground. This wind shear exponent along with the meteorological tower data, was then used to extrapolate the wind speeds at hub height using the power law vertical extrapolation method.

D2. Measurement Analysis Results

D2.1 Overall Measurement Analysis Results

Sources of existing noise commonly observed in the area were natural sounds such as birds calling, wind noise, and rustling vegetation. Other sources of noise included distant traffic at some locations (Highway 90, and Galbraith Line Road), local traffic, agricultural operations, dog barks, and aircraft passing overhead. The following general observations about the existing sound levels in the study area can be drawn from the measurement results:

- In general, local and distant traffic are the most common sources of existing sound. State Highway 90 and Galbraith Line Road are significant sources of existing sound and consistently influence sound levels at the locations S2 and F1 during both daytime and nighttime.
- Noise levels at all sites show a diurnal pattern, with daytime L₉₀ noise levels regularly reaching 40 dBA, and nighttime noise L₉₀ dBA levels in the 20s and 30s.
- From the level versus time figures, the effect of wind on sound levels is clear. For example, on June 28, 2024, L₉₀ sound levels reached 45 dBA during high winds. On most other days the L₉₀ sound level does not exceed 40 dBA.
- Measurements conducted under conditions conducive for wind turbine operations showed greater measured values by 2-3 dBA due to wind-induced noise.

The measured sound levels are summarized in Table D-3. The daytime L_{eq} across all six locations ranged from 39 to 53 dBA with an average of 44 dBA, and L₉₀ levels ranged from 30 to 35 dBA with an average of 32 dBA. The nighttime L_{eq} across all six locations ranged from 33 to 45 dBA with an average of 37 dBA, and L₉₀ levels ranged from 25 to 32 dBA with an average of 27 dBA. Plots of the measured noise levels versus time for each long-term measurement location can be found at the end of this appendix. A sample noise level versus time plot is shown in Figure D-2.

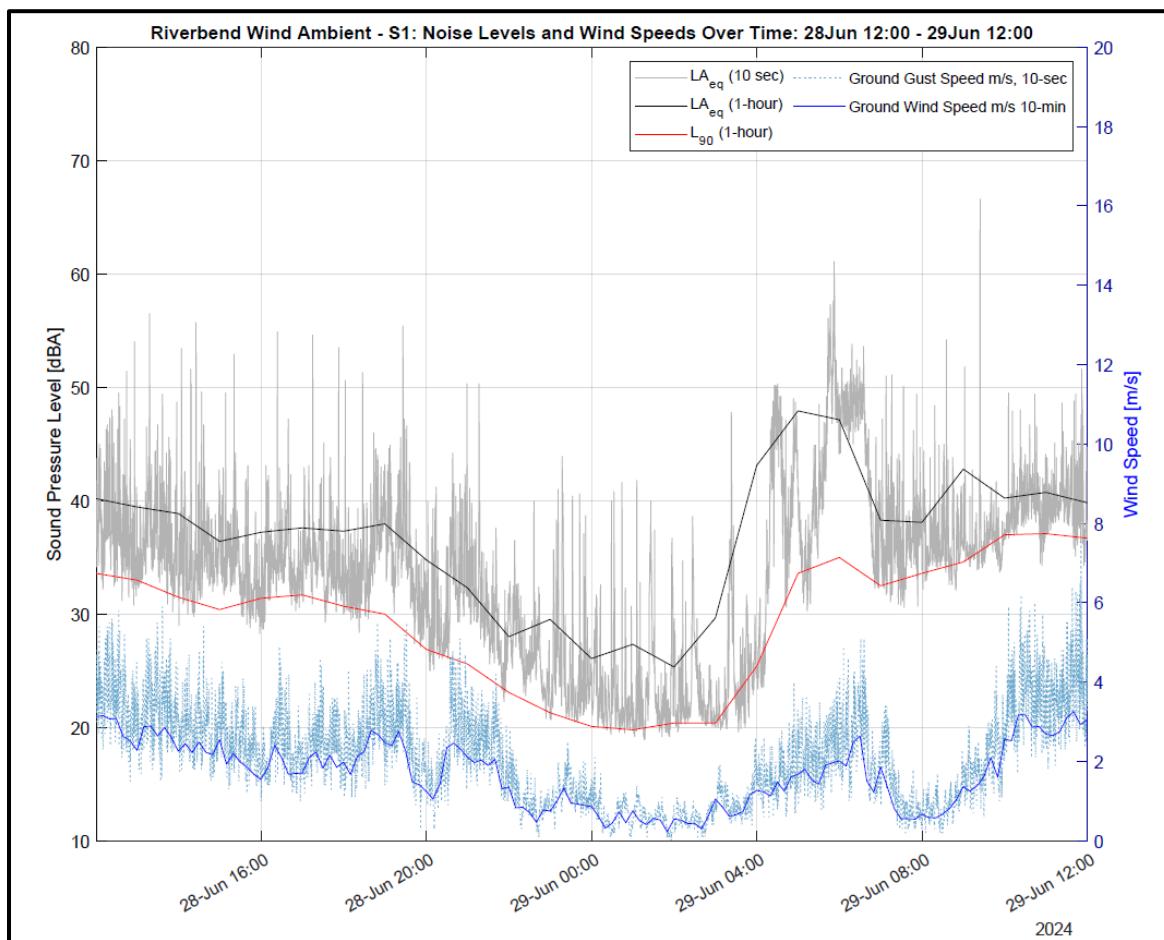

Figure D-2. Sample Time Plot of Long-Term Background Noise Levels at S1

D2.2 Wind Regression Analysis Results

The results of this analysis for all locations are shown on an L_{eq} , L_{10} , L_{50} , and an L_{90} basis in Table D-4. All the levels shown in the table were measured when the nearest turbines would be operating at full noise emissions. On an L_{90} basis, levels are as low as 19 dBA when there is a large degree of separation between ground-level and hub-height wind speeds, and as high as 45 dBA when there is little separation. On an L_{50} basis, levels are as low as 19 dBA and reach over 55 dBA but are generally in the mid 30's dBA. Figure D-3 shows an example result for location S1 during the nighttime period. In this example, mean L_{50} levels are approximately 30 dBA at a hub-height wind speed of 9 m/s or greater on average.

D2.3 Comparison of Existing and Predicted Noise Levels

Project noise levels were predicted and used to compare to measured ambient noise levels to quantify the noise impacts from the Project.

Noise levels were predicted using the method prescribed by International Organization for Standardization (ISO) Standard 9613-2:2024, Attenuation of Sound During Propagation Outdoors and implemented using the SoundPLAN v9.1 software program. Detailed information describing the input data and settings used with the ISO 9613-2:2024 method to predict noise levels from the Project can be found in the pre-construction report above. Table D-5 shows the measured ambient L_{eq}, L₁₀, L₅₀, and L₉₀ levels and the corresponding predicted levels for each measurement location. Also shown in the table is the total noise (existing ambient plus predicted noise level) and the increase over ambient levels from total noise levels.

Table D-5. Predicted Operational and Measured Ambient Noise Levels

Noise Contribution	Site	Vestas V162-6.0MW STE				Nordex 169-5.0 LNTE mode 0
